Packet 6: Chi-Square Test for Independence

After completing this material, you should be able to:

- calculate the expected count for any cell of a contingency table.
- find marginal distributions for a contingency table and use those to construct a side-by-side bar graph.
- compute chi-square contributions for any cell of a contingency table.
- conduct the chis-square test (with the aid of StatCrunch output) to determine if two categorical variables are related.

The <u>legalization</u> of medicinal marijuana has been a hotly contested subject. A survey conducted in April 2015 was undertaken to investigate whether a relationship exists between feelings on the legalization of medicinal marijuana (for/against) and political party (Republican/Democrat/Independent).

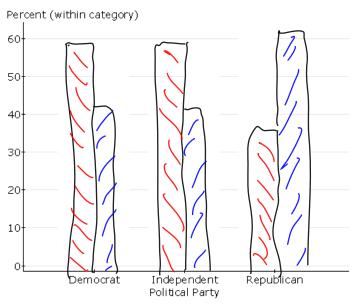

During this study, a total of 500 individuals were surveyed. For each American adult, what variables were recorded? Are these variables categorical or quantitative?

Because two variables were recorded for each individual, we need a way to organize this data. A **contingency table** categorizes counts on two (or more) categorical variables – in other words, this table summarizes the number of individuals in all possible combinations of categories. We can summarize the responses to the survey in the table below:

		Legalization	Sumb	
		Supports	Does not support	
Political Party	Democrat	116	84	200
	Republican	74	126	70 ⁰
	Independent	59	41	∫ ø ∅
C	guns	249	25/	500 =n

Instead of looking at the counts, let's split the table into marginal distributions — that is, what percentage of each political party surveyed gave each of the two responses?

	Supports	DPPOSL
Dems	116 = 585,	425.
Reps	74 - 375,	63 ⁵ .
Jak	59 /100 - 592.	4 (5,

Textbook pages: 18 – 24; 624 – 631

In order to determine if the differences are significant, we need to conduct a hypothesis test. One can never simply examine sample data and draw some conclusion about the population - we need to conduct a hypothesis test in order to determine if the results are significant.

What is the goal of the chi-square test for independence? To deferring whether two Catigorical variables are independent or not.

If we wanted to conduct this test on the legalization of marijuana data, what hypotheses would be tested?

Ho: P. Itical Party & support for medical marijuana are untelested (hence independent) Hair Political Party + support are related attract

In order to conduct a hypothesis test, we need some quantity to compare the observed counts from the survey to. This is referred to as the expected count (in other words, what should we have observed if the null hypothesis were true). Fill in the table below with the expected counts.

ran		Observed	Legalization of Marijuana		
Tofo	Counts		Supports	Does not support	
desi	Party	Democrat	116	84	
	Political P	Republican	74	126	
	Poli	Independent	59	41	
			249	25	

500 : 498 Support

_				1				
	Expected \	Legalization	Legalization of Marijuana					
	Counts	Supports	Does not support					
ty	Democrat	749 500 - 200 = 996	100-7	2 40				
Political Party	Republican	39.6	(00.4	902				
Po	Independent	249 - 100 = 49.8	, 50.2	(00				
		749	761	ı				

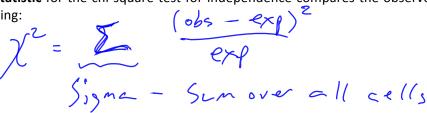

What do you notice when the observed (top table) and expected counts (bottom table) are compared?

Onite a differer! If they were similar it would support independence - but were not seeing that!

This formula will be given or

The test statistic for the chi-square test for independence compares the observed and expected counts. Its formula is

What is the Chi-Square distribution?

Different Ran a normal, for swe!

In statistical inference, there are several common distributions used for inference. In addition to the normal distribution (which we have already used), the chi-square distribution is also a common distribution used for inference.

How is the chi-square distribution used to find a probability?

Comprete Z?; lock to the even to the right of X2

for the prob of a X2 that

extrue or nore so, Conjul_ to to t decide it se reject a

Chi-Square Distn, df=3

In general, we won't calculate the chi-square test statistic (the calculation can be tedious) or the p-value associated with the test. Instead, we will rely on StatCrunch output for our calculations. Let's look at the StatCrunch output for the legalization of marijuana example: -habil.77

	Supports	Does not support	Total	Chi-Square	tes	t:			2
Democrat	116 (99.6)		200	Statistic	DE	Value	P-value	DATE	7
	(2.7)			Chi-square	2	21.87235	<0.0001	~ ~2	
Republican	74 (99.6) (6.58)	(100.4)	1	obser	ve			ot A.	
Other	59 (49.8) (1.7)	(50.2)	100	· ·		tel	~ (2		
Total	249	251	500	- conto	bu	tion to	$\chi - +$	\sigma \sigma	

STA 205 Notes Buckley Fall 2016 Dat (c1).

10

Complete the appropriate hypothesis test using a significance level of 0.05 to determine if political party and support of legalization of marijuana are related, and is defined as

legalization of marijuana are related, on independent.

He is no tropic

The is party to opinion are independent. He is no tropic

To Lo, 05; reject th, if prob. (produce) < L.

The independent of prob of X2 that extreme

or more so) is so vidiculously small (<< d),

we reject the null of independence in favor to

dependence: Kepblican favor (egalization less than

Example: All new drugs must go through a drug study before being approved by the FDA. A drug study typically includes clinical trials whereby participants are randomized to receive different dosages as well as a placebo. To control as many factors as possible, it is best to assign participants randomly across the treatments. A recent study for a new drug consisted of two dosages (10mg, 20mg) and a placebo. Those who designed the study would like to know if the dosage assigned was related to the participants' gender. The responses are summarized in the StatCrunch output below:

	10mg	20mg	Placebo	Total
Female	54	56	60	170
	57.33	55.33	5235	
	0.1938	0.008	0.124	
Male 🐠	~ 32	27	26	85
مع	28.67	27.67	28.67	
•	(3868)	0.0161	0.2481	
Total	86	83		255

Compute the **expected** number of females receiving the placebo. What does this quantity mean?

86 - 170 = 57.33 of kore

Pelative fregues the services

The services of ferrods of services

The services of serv

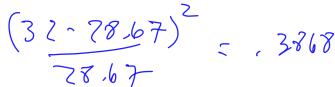

Find the marginal distribution for each gender by filling in the tables below.

		Dosage	
	10mg	20mg	Placebo
Female	54 = 31,762	56, 37.94%	60 = 35.29 &

		Dosage	
	10mg	20mg	Placebo
Male	37.67%	31.74 7.	30.59%

Based on these distributions, do you believe gender is somehow related to dosage? Explain.

There are differred, but not that big; could just be random effects. Compute the chi-square contribution for male participants who were given 10mg of the drug.

Using the StatCrunch output below, conduct the appropriate test to determine if there is a relationship between gender and the dosage received. Use a significance level of 0,01.

Chi-Square	test for	independence:
------------	----------	---------------

Measure	DF	Value	P-value
Chi-Square	2	0.9775848	0.6134

1) H; independence of genele or dosage Hai tregar related, E) La, 01; reject H, infavor of Haif p-value < La = 101

(3) TS, X2 = S776 with proclare = .6134_ So pound se = prob > a. (4) Since the proche is > a, we fail to riject a noll of infendence.

What assumptions must be satisfied for the chi-square test of independence to be valid?

De dose are from a random sample

De experted counts is > 5 or more
in each cell.

Example: A sample of 1000 traffic crashes occurring in either Kentucky or Ohio was selected from the National Highway Safety Traffic Administration database. For each crash, it was noted whether or not alcohol was involved in the accident. A reporter has questioned whether there is a relationship between alcohol involvement and the state in which the accident occurred. The information gathered is summarized in the StatCrunch output provided.

 Compute the number of accidents one would expect to involve alcohol in KY if there is no relationship.

Yes:
$$\frac{206.374}{1000} = 77.04$$

No: $\frac{754.206}{1000} = \frac{296.96}{374}$

Contingency table results:

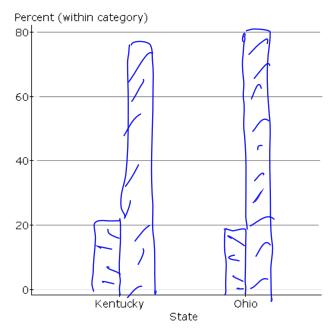

_	•		
	No	Yes	Total
Kentucky	289 756.94 (0.21)	77.0 Y (0.82)	374
Ohio	505 \\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\	121 121.% (0.49)	626
Total	794	206	1000

	Statistic	DF	Value	P-value	
	Chi-square		1.65	0.1986	
					_
,214	, 758,	(3 <i>f</i>	.49=		

 Fill in the tables below with the marginal distributions for each state. Then create a side-by-side bar graph comparing the percentages for the two states.

	Alcohol – yes	Alcohol – no
KY	75 1374 = 27,73	77.27).

	Alcohol – yes	Alcohol – no
ОН	19,332	8 67 50

Conduct the appropriate test to address the conjecture made by the reporter. Use a significance level of 0.05.

Ho; independence of state & alcohol related crashes

Ha; they are related.
